Project 1 (1-3048), Task 304802

(Prepared under Contract No. AF 33(616)-8287
by Air Products and Chemicals, Inc., Allentown,
Pennsylvania; Jerome Brewer, author)

FOREWORD

This report was prepared by Air Products and Chemicals, Inc., under USAF Contract No. AF 33 (616)-8287. This contract was initiated under Project No. 1 (1-3048), "Aviation Fuels", Task No. 304802, "High Energy Fuels". The work was administered under the direction of the Directorate of Materials and Processes, Aeronautical Systems Division, Wright-Patterson Air Force Base, Ohio, with Messrs. James H. L. Lawler and Perie R. Pitts, Jr. of ASD acting as Project Engineers.

This report covers work conducted from May 1961 to September 1961.

The work covered in this report was conducted by Dr. Jerome Brewer, Project Leader, supervised by Dr. J. M. Geist, Associate Director, and directed by Dr. Clyde McKinley, Director, Research and Development Department. Dr. Leonard Wenzel of Lehigh University, and Mr. J. A. Carlson, Jr., Manager of Advanced Projects, participated in the review of the work performed. Special thanks are due Mr. G. M. Gigliotti, for his technical editorship, and Miss Fay A. Jones, for preparing the manuscript.

ABSTRACT

The following data, which were compiled from published literature, are presented graphically as a function of temperature and pressure:

Viscosity of Nitrogen, Viscosity of Oxygen, Viscosity of Air, Viscosity of Saturated Liquid (Oxygen, Nitrogen, and Mixtures), Vapor-Liquid Equilibrium Ratios: Oxygen-Nitrogen System, Dew Points: Oxygen-Nitrogen System, Bubble Points: Oxygen-Nitrogen System, Thermal Conductivity of Nitrogen, Thermal Conductivity of Oxygen, Thermal Conductivity of Saturated Liquefied Nitrogen and Oxygen, Density of Oxygen, Density of Nitrogen, Prandtl Number of Nitrogen, and Prandtl Number of Oxygen.

For each of the above properties a discussion of their critical evaluation was made. Two complete sets of curves were presented, one set with experimental and correlative data points and one set without data points. A complete bibliography of the sources used for each property are given as well as a master bibliography which include all sources consulted or related to the subject. Tables of tabulated values of the properties used to construct the various graphs are presented.

PUBLICATION REVIEW

This report has been reviewed and is approved.

I. INTRODUCTION

This report presents in graphical and tabular form thermodynamic data on oxygen and nitrogen. The data include viscosity, vapor dew point, liquid bubble points, vapor-liquid equilibrium ratios, thermal conductivity, density, and Prandtl Number of the two elements, as well as mixtures thereof, in the pressure range of 10 psia to 10,000 psia and the temperature range of -330°F to 500°F.

On the following pages may be found the complete series of charts, without data points or references, presented for easy reference. In subsequent sections may be found the selected bibliography, discussion of the data, and the specific charts showing data points and their source. Also included in this report are a complete and up-to-date bibliography, and a tabulation of the data used in constructing the charts.

Manuscript released by the author September 1961 for publication as an ASD Technical Documentary Report.

II. SUMMARY

The thermodynamic properties of nitrogen and oxygen (including some data on their mixtures) such as viscosity, vapor-liquid equilibrium ratios, dew points, bubble points, thermal conductivity, density of gas and liquid, and Prandtl Number, are presented as a function of temperature and pressure in Figures 1 to 19 inclusive. These data are based on a critical evaluation of the published literature up to July 1961.

III. DISCUSSION AND CRITICAL EVALUATION

In the following subsection is presented a discussion of the data and an evaluation of the agreement among the several investigators whose work was selected for inclusion in this report. The sources of the data pertaining to each chart are listed and the experimental and analytical procedure used by each investigator is described and the accuracy obtained is discussed. Following each discussion is the subject chart with the data points plotted. The data points used in the plots may be found in tables in the Appendix.

A. Viscosity of Nitrogen

Sources of Data:

1. Baron, J.D., J.G. Roof, and E.W. Wells, "Viscosity of Nitrogen, Methane, Ethane, and Propane at Elevated Temperatures and Pressure", Journ. Chem. Eng. Data 4, 283-288 (1959).
2. Brebach, W.J. and G. Thodos, "Viscosity-Reduced State Correlation for Diatomic Gases", Ind. Eng. Chem. 50, 1095-100 (1958).
3. Johnston, H.L. and K.E. McCloskey, "Viscosities of Several Common Gases between 90°K and Room Temperature", Journ. Phys. Chem. 44, 1038 (1940).
4. Kestin, J. and W. Leidenfrost, "Absolute Determination of the Viscosity of Eleven Gases Over a Range of Pressures", Physica 25, 1033-62 (1959).
5. Michels, A. and R.O. Gibson, "The Measurement of the Viscosity of Gases at High Pressures -- The Viscosity of Nitrogen at 1000 Atms.", Proc. Roy. Soc. (London) A134, 288-307 (1931).
6. Ross, J.F. and G.M. Brown, "Viscosities of Gases at High Pressures", Ind. Eng. Chem. 49, 2026-33 (1957).

Figure 20 shows the data points obtained from the various literature sources. The atmospheric pressure line is obtained at lower temperatures from Johnston and McCloskey (3), while at temperatures above 100°F the data of Baron, Roof, and Wells (1) were used. Data on viscosity of compressed N₂ were available at temperatures from -60 to +275°F and pressures up to 10,000 psi (1, 4, 5, 6). These data were consistent except for the highest pressure data of Michels and Gibson (5), and were also used as primary information sources. At temperatures below -60°F the viscosity of nitrogen for the isobars from 500 to 10,000 psi were obtained through correlations of Ross and Brown (6) and of Brebach and Thodos (2). These correlations agreed within about $\pm 10\%$ in the area where they were both usable. Brebach and Thodos (2) also gave information allowing the saturation boundary and the viscosity of sub-critical temperatures to be obtained.

Baron, Roof, and Wells (1), used a transpiration viscometer in their measurements. Gas in a closed glass loop was removed through a capillary section by the fall of a mercury pellet in the opposite leg of the loop. The glass loop was enclosed in a thermostatic pressure vessel and the pressure within the loop balanced against that in the vessel. The position of the mercury pellet was sensed by tungsten contacts, and its size was adjusted to give gas Reynolds numbers in the capillary well below 2000. The rate of fall of the mercury pellet was kept independent of surface tension effects by scrupulously cleaning the glassware and by careful design of the tungsten contacts. Temperature was controlled to 0.05°F and pressure to 1 psi. The data were internally consistent to within $\pm 1\%$. The only external comparison that can be made is against the data of Michels and Gibson (5) extrapolated to 175°F. Differences are generally less than 3%, with the Baron data giving lower values of viscosity at low pressure and higher values at pressures above 2000 psi. Michels and Gibson (5) also used a transpiration method, and obtained data at about the same accuracy as that of Baron (1).

Ross and Brown (6) also used a transpiration viscosimeter, in which gas flow was driven by a pair of instrument bellows attached to the two ends of the capillary tube. The use of bellows allowed viscosity to be determined at temperatures above -50°C. Proper interpretations of results required extensive calibration and connections but comparisons with the data of Michels and Gibson (5) and internal comparisons lead to an estimated accuracy of $\pm 1\%$.

At temperatures below -60°F, primary reliance was placed upon the correlation of Brebach and Thodos (2). They found that residual viscosity ($\mu - \mu_0$) was a function of the fluid density alone. The symbol represents the viscosity of the fluid at the desired temperature but at atmospheric pressure. Data for nitrogen gas at all pressures and for nitrogen liquid could be correlated in this way. From a knowledge of the density of nitrogen obtained from the literature, the viscosity of nitrogen was calculated for all desired values of temperature and pressure. The results have been compared with 198 data points for nitrogen obtained from experiment with a root mean square deviation of 1%.

The agreement found between the several experimenters leads to high confidence in the data for viscosity above -60°F. At pressures below 8000 psi and temperatures above -60°F the data should be accurate within $\pm 2\%$. For temperatures below -100°F and for pressures higher than 1 atmosphere the

results are less reliable, but probably within $\pm 5\%$. In part of this temperature range the viscosity isobars became almost vertical as the temperature is lowered and these regions of highly negative slope are in greatest doubt. An accuracy of $\pm 10\%$ is expected.

The tabulated data are given in Table I.

B. Viscosity of Gaseous Oxygen

Sources of Data:

1. Brebach, W.J. and G. Thodos, "Viscosity-Reduced State Correlation for Diatomic Gases", Ind. Eng. Chem. 50, 1095-100 (1958).

6. Kiyama, R. and T. Makita, "The Viscosity of Carbon Dioxide, Ammonia, Acetylene, Argon, and Oxygen Under High Pressures", Rev. Phys. Chem. (Japan) 22, 49 (1952).
7. Kiyama, R. and T. Makita, "Improved Viscometer for Compressed Gases and the Viscosity of Oxygen", Rev. Phys. Chem. (Japan) 26, 70 (1956).
8. Luker, J. A. and C. A. Johnson, "Viscosity of Helium, Oxygen, Helium-Oxygen, Helium-Steam, and Oxygen-Steam Mixtures of High Temperatures and Pressures", J. Chem. Eng. Data 4, 176 (1959).
9. Trantz, M. and R. Zink, "Viscosity, Heat Conduction and Diffusion in Gas Mixtures, XII, Viscosity of Gases at High Temperatures, Am. Physik (5) 7, 427 (1930).

Data for the viscosity at atmospheric pressure at temperatures below ambient were taken from Johnston and McCloskey (4), and at higher temperatures from Hilsenrath and Touloukian (3). These data were confirmed by the low pressure data from other sources (1, 2, 5, 6, 7, 8).

Data for viscosity of compressed oxygen are available at temperatures of ambient and above (2, 5, 6, 7, 8) at pressures up to 2000 psia. No direct data were found for lower temperatures or for higher pressure regions. In these areas the correlation of Brebach and Thodos (1) was used.

The atmospheric data of Johnston and McCloskey (4) along with that of Trantz and Zink (9) and four other investigators were compared by Hilsenrath and Touloukian (3). Agreement within $\pm 1\%$ was found in all the data sources at temperatures below 1000°K. Thus a 1% reliability can be expected in these data.

Experimental data on viscosity of oxygen at pressures above atmospheric are shown in Figure 21 (2, 5, 6, 7, 8). The data are extremely limited in scope and are not in good agreement. Only the data by Kestin (5) appear to be reliable and these agree with the correlation of Brebach and Thodos (1).

The oxygen viscosity data are well substantiated at atmospheric pressure where an accuracy of $\pm 1\%$ can be expected. The affect of pressure can be obtained only from a correlation based primarily on nitrogen data. Experimental data showing the effect of pressure are scanty and contradictory. Thus the data presented for the viscosity of compressed oxygen are probably accurate to $\pm 10\%$ in the pressure range below 3000 psi and at temperatures above 0°F. Outside of this region an accuracy of $\pm 20\%$ can be expected.

The tabulated data are given in Table II .

C. Viscosity of Air

8. Johnston, H. L. and K.E. McCloskey, "Viscosities of Several Common Gases between 90°R and Room Temperature", J. Phys. Chem. 44, 1038 (1940).
9. Kestin, J., and W. Leidenfrost, "Absolute Determination of the Viscosity of Eleven Gases over a Range of Pressures", Physica 25, 1033-62 (1959).
10. Kestin, J., and K. Pilarczyk, "Measurement of the Viscosity of Five Gases at Elevated Pressures by the Oscillating Disk Method", Trans. ASME 76, 987 (1954).

11. Nasini, A. G., and G. Pastonesi, "Viscosity of Air up to 200 Atmospheres", Gazz, Chimica Italiana 63, 821 (1933).

Data at atmospheric pressure and at temperatures below ambient were taken from Johnston and McCloskey (8). For higher temperatures the correlation of Hilsenrath and Touloukian (5), based on the experimental data of 20 investigators was used. This correlation is:

$$\mu \times 10^7 = 145.8 (T)^{3/2} / (T + 10.4)$$

where

μ = viscosity, poise

T = temperature, °K

The high pressure data presented have been calculated from the correlation of Brebach and Thodos (1).

Eleven sources of data on the viscosity of air at atmospheric pressure were analyzed and compared by Hilsenrath and Touloukian (5). These included the data of Johnston and McCloskey (8) in the low temperature range. The data sources agreed within $\pm 1\%$ at temperatures below 800°K. Thus the data at atmospheric pressure reported here should be reliable within $\pm 1\%$.

Several investigators have measured the effect of pressure on the viscosity of air (3, 4, 6, 9, 10, 11). However, all of these data were collected at temperatures equal to or greater than ambient and at pressures below 6000 psia. Some of these data are compared with the results reported in Figure 22. The data of Glaser and Gebhardt (3) were obtained with a falling ball viscosimeter and are reported only graphically. The original source gives no estimate of accuracy. The data do not agree with the present results, even at one atmosphere. The data of Kestin and Leidenfrost (9) and of Golubev (4) agree well with the results reported. The greatest discrepancy is about 2% in the viscosity value of Golubev at 2000 psia and 100°C. Hilsenrath shows that the data of Iwasaki (6) and of Nasini and Pastonesi (11) do not agree with that of Golubev. Thus only the results of Kestin (9, 10) and of Golubev (4) are consistent with the calculated values presented here. Despite the limited range of these data, they lend strong support to the calculated values, since the Kestin (9, 10) data have been obtained so carefully.

The correlation of Brebach and Thodos (1) is the major source of the data presented. This correlation is based on the corresponding states principle and the extensive available data on nitrogen. Since air is largely nitrogen, this approach should be applicable, and has been frequently used in the past. In this case, the residual viscosity of nitrogen was found to be a function of the density of nitrogen. A similar relation was found for other gases. This relation was used to extend the nitrogen data into regions where data were lacking. Although the correlation predicts the available data by about + 3%, it is probably reliable only to within $\pm 10\%$ in the area near the critical temperature. The correlation gives the viscosity in the reduced form, μ / μ_c . The critical viscosity, μ_c , was taken as 0.048 lb/ft-hr, a compromise between the value of 0.0496 given by Johnson, et al (7), and that of 0.0473 given by Codegone (2).

Figure 22, showing the viscosity of gaseous air, is based on experimental data for viscosity at atmospheric pressure, and on a corresponding-states correlation for high pressure data. The high pressure data are corroborated with experimental data only in the ambient temperature range.

The data at atmospheric pressure are probably reliable to $\pm 1\%$. The high pressure data are probably reliable to $\pm 5\%$ at temperatures above 0°F , and pressures below 2000 psia, and to $\pm 10\%$ at temperatures below 0°F and at pressures above 2000 psia.

The tabulated data are given in Table III.

D. Viscosity of Saturated Liquids

Sources of Data:

4. Rudenko, N. S., "Viscosity of Liquid Oxygen, Nitrogen, Methane, Ethylene, and Air", J. Exptl. Theoret. Phys (USSR) 9, 1078 (1939).
5. Rudenko, N. S. and L. V. Shubnikow, "Viscosity of Liquid Nitrogen, Carbon Monoxide, Argon and Oxygen and its Dependence on Temperature", Physik.Z. Sowjetunion 6, 470-7 (1934).
6. Van Itterbeek, A. and O. van Paemel, "Determination of the Viscosity of Liquid Hydrogen and Deuterium", Physica 8, 133 (1941).

Oxygen

The data of Rudenko and Shubnikow (5) were plotted over the range -361.8° to -315.7°F . Values from Van Itterbeek and Van Paemel (4) were plotted over the range -336.1 to -297.3°F and showed close agreement with the data of Rudenko and Shubnikow in the common temperature range. The spread of points about the smoothed curve over the range, -361.8 to -315.7°F , is $\pm 2-3\%$ in most cases, as shown in Figure 23.

At higher temperatures, the data of Rudenko (4) over the range, -259.9 to -182.3°F , indicate that the viscosity-temperature curve should be hyperbolic (concave-upward), even at temperatures very close to the critical temperature (-181.1°F). However, from considerations of continuity of the saturation curve, and the

shape of the saturated vapor viscosity curve, it was believed that the values of Rudenko (4) were unreliable over the range, -233.3 to -182.3°F , and, instead, values from the reduced viscosity correlation of Brebach and Thodos (1) were used to define the curve near the critical point. The range over which these values were used was -225.7 to 181.1°F . It is significant to note that although Brebach and Thodos (1) claim large deviation from experimental values when the reduced correlation is used for liquid oxygen, the experimental values, in this case, were probably those of Rudenko (4), which seem very doubtful. In view of this, it does not seem possible to estimate the uncertainty introduced by using the correlation of (1).

The tabulated data are given in Table IV.

Nitrogen

Two sets of data were plotted from Brebach and Thodos (1). Data were taken from a plot of μ_r vs. T_r which utilized literature values in drawing a saturated liquid curve. The range used was approximately -335°F to -255°F . Another set of data was taken from a plot of residual viscosity, $\mu - \mu_g$ vs. the density, in which the temperature range used was -340°F to -235°F . Some uncertainty exists in the values taken from these plots since the graphs were small and contained no auxiliary grid lines. Moreover, one of the plots has a very large slope in the region from which some values were taken. The estimated uncertainty in the reading of these graphs is approximately 5 to 10%. Hence, values from these were not assigned primary weight in plotting the viscosity curve, where experimental data were available.

Primary weight was given to the data of (3) and (6) in drawing the curve from -346°F to -280°F . At higher temperatures, the available data from (3) indicates that the $\mu - T$ curve is hyperbolic, while considerations of continuity at the critical point lead to the conclusion that the curve must have an infinite slope at the critical temperature and that an inflection point exists. This inflection point was drawn at about -270°F , and, using some values from (1) as a guide, the curve was extended to the critical viscosity as shown in Figure 23. In doing so, the values from (3) and from Brebach and Thodos (1) were not given primary weight.

Agreement of values from all sources in the range, -346 to -280°F , is good. The spread of points about the curve in this range averages about $\pm 2\%$. The points from (3) were given primary weight over this range. At temperatures above -280°F , uncertainties in the values as high as $\pm 10\%$ are possible.

The tabulated data are given in Table V.

Nitrogen-Oxygen Mixtures

The correlation for the viscosities of liquid mixtures suggested by Hirschfelder, et al (1) was used to construct curves for 25, 50, and 75% O₂ in N₂-O₂ mixtures of Figure 23. The correlating equation due to Eyring was as follows:

$$\log \mu_{\text{mix}} = X_1 \log \mu_1 + X_2 \log \mu_2$$

Here X_1 and X_2 are mole fractions, μ_1 and μ_2 are viscosities of the pure components, and μ_{mix} is the viscosity of the mixture, all at the same temperature. The temperature range covered was from -340 to -260°F. In this temperature range, the most reliable viscosity data for pure oxygen and pure nitrogen were obtained. Auxiliary viscosity graphs gave a virtual straight line when $\log \mu$ was plotted against the reciprocal temperature over this range. At higher temperatures, near the critical, the uncertainty of the pure component viscosities increased considerably.

The tabulated data are given in Table VI.

The 100% oxygen data on the dew and bubble point curves is the vapor pressure of oxygen. This was taken directly from the data of Hoge (12). Similarly the 0% oxygen curves are identical to the vapor pressure of nitrogen. These data were obtained from Michels et al (18), Friedman and White (9), Dodge and Davis (7), and Henning (11).

These vapor pressure relations also determine the points of intersection of

These vapor pressure relations also determine the points of intersection of the K-value curves with the $K=1$ line, and the ends of these lines in the sub-critical region. The critical point for 21% oxygen was taken as that for air reported by Kuenen and Clark (15), while the rest of the critical envelope is that of Kuenen, Verschoyle, and van Urk (16). The K-value charts are not extended into the critical region.

Data in the two-component region on the dew and bubble point charts and on the K-value plots were obtained from Dodge and Dunbar (8). These investigators report isotherms and isopiistics for the oxygen-nitrogen system over the entire composition range. Pressures ranged from 0.75 to .32 atm. and temperatures from 72 to 133°K. These results were correlated by three equations which allow interpolation. These interpolation formulas were used in constructing the charts discussed here.

In obtaining the dew point plots the original data of Dodge and Dunbar (8) were plotted as isotherms on P-x and P-y coordinates. Values from the P-y coordinates are not included here.

In obtaining the K-value charts the interpolation equations of Dodge and Dunbar were used to obtain tabular K data as functions of X_{O_2} and T, and also to obtain tabular P data as functions of X_{O_2} and T. These tables were used simultaneously to obtain K as functions of P and T.

The vapor pressure data for oxygen (12) and for nitrogen (7, 9, 11, 18) appear highly reliable. The various sources for nitrogen agreed with each other within a maximum deviation in pressure of $\pm 1\%$. The data of Hoge (12) for oxygen, when compared with earlier investigators (5, 10) show maximum deviations of 0.5%. Thus a reliability within $\pm 1\%$ can be expected for the 0% and 100% oxygen data.

The critical locus is somewhat less precisely determined. Though the data of Kuenen and Clark (15) and of Kuenen, Verschoyle and van Urk (16) are internally smooth and in substantial agreement, the nature of measurements in the critical region makes it almost impossible to determine precise phase boundaries. Thus a precision of $\pm 1^\circ\text{F}$ must be expected in this region.

The data of Dodge and Dunbar (8) for the two-component region were obtained in a vapor-recycle equilibrium cell. Temperature control was obtained by control of pressure over boiling liquid oxygen. Temperatures were measured with calibrated thermocouples to an accuracy of about $\pm 0.1^\circ\text{C}$. Pressures were measured

by manometers and a dead-weight pressure gage. Comparative measurements agreed within an average deviation of 0.008%. Sampling and analysis by absorption in potassium pyrogallate solution give check samples agreeing with 0.2%. These data have been examined closely by many investigators over the years, two recent cases being those of Latimer (17) and Din (5) and Cockett (3). In all cases the Dodge and Dunbar data have been found to be the best available. Din reports that the temperature scale used by Dodge and Dunbar was in error by 0.5°C at the methane point, reflecting similar errors in the final data at the higher temperatures. He also reports that analysis of the data shows that they lack thermodynamic consistency at high temperatures and pressures. Thus these data are probably accurate to 0.1°C at pressures close to atmospheric but to about 1°C at pressures above 100 psia. Above -240°F the data have been extrapolated. Although a reduced accuracy would thus be expected, the limits imposed by the 0 and 100% oxygen curves and the critical locus probably ensure a continuation of the accuracy limit of 1°C.

Summarizing graphs showing the dew points, bubble points, and oxygen and nitrogen K-values have been prepared and presented in Figure 24 and 27 inclusive. In the single-component limits these are based on extensive experimental values of many investigators (1, 4, 7, 9, 12, 16, 18) accuracy should be better than 0.1°F. In the two-component region the data of Dodge and Dunbar (8) were the major sources but the data of Din (4) and Cockett (3) were also used. These data are accurate to 0.1°F in temperature or 2% in K-value at pressure below 100 psia. At higher pressures accuracy is expected to be less, in the order of 1°F in temperature or 5% K-value.

The tabulated data are given in Table VII.

F. Thermal Conductivity of Nitrogen

Sources of Data:

1. Hilsenrath, J., et al., "Tables of Thermal Properties of Gases", NBS Cir. 564 (1955).
2. Johnson, V. J., "A Compendium of the Properties of Materials at Low Temperatures", (Phase I) WADD-TR-60-56, Oct., 1960, p. 3.004.
3. Lenoir, J. M., W. A. Junk, and E. W. Comings, "Measurement and Correlation of Thermal Conductivities of Gases at High Pressures", Chem. Eng. Prog. 49, 539-42 (1953).
4. Michels, A., "Viscosity and Heat Conductivity of Gases (and Liquids) in the Neighborhood of Condensation Region", Proc. Intern. Symp. on Transp. Process in Stat. Mech., Brussels, 1956, 365-375 (Pub. 1958).
5. Nuttall, R. L. and D. C. Ginnings, "Thermal Conductivity of Nitrogen from 50° to 500°C and 1 to 100 Atm.", J. Res. NBS 58, 276 (1957) (Research Paper 2760).
6. Owens, E. J. and G. Thodos, "Thermal Conductivity-Reduced State Correlation for the Inert Gases", A. I. Ch. E. Journal 3, 459-60 (1957).

The data have been presented graphically in Figure 28 covering thermal conductivity values of 0.004 to 0.029 Btu/Hr-Ft-°F, and in inset furnishing values to approximately 0.085 Btu/Hr-Ft-°F. The inset was used because some experimental data at values above 0.29 Btu/Hr-Ft-°F were available; it was also desired to show the lower range as accurately as possible.

The reduction envelope was constructed using the correlation of Owens and Thodos (6) and from which the critical thermal conductivity was taken to be 0.02099 Btu/Hr-Ft-°F. The saturated liquid curve was not included in the inset. At 14.7 psia, experimental data from the NBS Compendium (2) and values from the NBS Circular 564 (1), based on the work of Keyes and Stops, were available. The values from the NBS Circular 564 (1) were not given primary weight in plotting this

isobar, except at higher temperatures, where they were the only experimental data available. The values from the NBS Circular 564 (1) were not given primary weight in plotting this isobar, except at higher temperatures, where they were the only experimental data available. Some experimental values were available up through 2000 psia. The data from the NBS Compendium (2) were used at low temperatures, and scattered experimental values from Lenoir, et al (3) and Nutall and Ginnings (5) were also included in plotting the isobars. Data points in the high temperature regions were obtained using the correlations of Lenoir, et al (3) and Owens and Thodos (6). The isobars higher than 2000 psia were plotted using only the correlation from Owens and Thodos (6).

In all cases, experimental data were more heavily weighted than correlative values in plotting the curves. The data from Hilsenrath, et al (1) are claimed to be reliable to within about 2%. Nutall and Ginnings (5) claim an uncertainty of only 0.5 - 1.5%, but their results differ substantially from those of the other investigators. Lenoir, et al (3) admit that their molecular model may be oversimplified; this would decrease the reliability of their correlation. Owens and Thodos (6), comparing correlation values to experimental values, find an average deviation for the correlation of 2.6%, with a maximum deviation of 8.4%. In view of the above discussion, it is probable that for the curves or parts of curves determined from experimental data, the uncertainty is no greater than 2 to 3%. For the regions where correlations were used, an average uncertainty of ± 3 to 4% with maximums approaching ± 9 to 10% may be expected.

The tabulated data are given in Table VIII.

G. Thermal Conductivity of Oxygen

Sources of Data:

1. Hilsenrath, J. et al, "Tables of Thermal Properties of Gases", NBS Cir. 564, 425 (1955).
2. Johnson, V. J., "A Compendium of the Properties of Materials at Low Temperatures" (Phase I) WADD-TR-60-56, Oct., 1960, p. 3.005.
3. Lenoir, J. M., W. A. Junk, and E. W. Comings, "Measurements and Correlation of Thermal Conductivities of Gases at High Pressures", Chem. Eng. Prog. 49, 539 (1953).
4. Owens, E. J. and G. Thodos, "Thermal Conductivity-Reduced State Correlation for the Inert Gases", A. I. Ch. E. Journal 3, 459-60 (1957).
5. Tsederberg, N. V. and D. L. Timrot, "Experimental Determination of the Thermal Conductivity of Liquid Oxygen", Zhur. Tekh. Fiz. 26, 1849 (1956).
6. Ziebland, H. and J. T. A. Burton, "The Thermal Conductivity of Liquid and Gaseous Oxygen", Brit. J. Appl. Phys. 6, 416, (1955).

The greatest amount of experimental data for thermal conductivity of oxygen was found for a pressure of 1 atm. At temperatures below 0°F, the 14.7 psia isobar was obtained from the data of the NBS Compendium (2), Tsederberg and Timrot (5), and Ziebland and Burton (6). At higher temperatures, the data plotted were those of Tsederberg and Timrot (5). At the lower temperatures, the deviation of points from the plotted curve as shown in Figure 29 averages about +2%, with a maximum of approximately 5%. The data of Tsederberg and Timrot (5) and Ziebland and Burton (6) were weighed about equally, since both sets of data were experimental. At higher temperatures, there was virtually no deviation of the points on the 14.7 psia isobar. The saturated vapor curve was plotted entirely from the correlation of Owens and Thodos (4), according to whom, the average deviation from experimental values is 2.7% for gaseous oxygen.

Experimental data were available from Tsederberg and Timrot (5) and Ziebland and Burton (6) in the regions containing the minima in the isobars through 1500 psia. Experimental agreement is particularly good for the 1000 psia isobar in that region, the deviation of data points being about $\pm 1\%$. The correlation of Owens and Thodos (4) and values obtained from Lenoir, et al (3) were used to determine the isobars at the higher temperatures, where no experimental data were available.

The isobars from 2000 psia to 4000 psia, inclusive, were constructed almost entirely from Owens and Thodos (4) and Lenoir, et al (3). The deviation of the data points was $\pm 1\%$ or less for the 2000, 2500, and 3000 psia isobars, and reached a maximum of 2% for the 3500 psia isobar.

In summary, the error in the thermal conductivity of oxygen in those portions which were determined mainly by experiment is probably $\pm 2\%$, while the error in those portions which were determined from correlations is about $\pm 4 - 5\%$.

The tabulated data are given in Table IX.

H. Thermal Conductivity of Saturated Liquid Nitrogen

1. Borovik, E., A. Matveev and E. Panina, "Thermal Conductivity of Liquid Nitrogen, Carbon Monoxide, Methane, and Ethylene", J. of Tech. Physics (USSR) 10, 994 (1940).
2. Owens, E. J. and G. Thodos, "Thermal Conductivity-Reduced State Correlation for the Inert Gases", A.I. Ch. E. Journal 3, 459-460 (1957).
3. Powers, R.W., R.W. Mattox, and H. L. Johnston, "Thermal Conductivities of Condensed Gases. I. The Thermal Conductivity of Liquid Nitrogen between 65° and 90°K", J. Am. Chem. Soc. 76, 5968-73 (1954).
4. Riedel, L., "A New Universal Vapor-Pressure Equation. I. The Extension of the Theorem of Corresponding States", Chem. Ing. Tech. 26, 83 (1954).
5. Riedel, L., "A New Universal Vapor-Pressure Equation. II. Liquid Density in the Saturated State", Chem. Ing. Tech. 26, 259 (1954).
6. Riedel, L., "A New Universal Vapor-Pressure Equation. III. Critical Coefficient, Density of Saturated Vapor, and Latent Heat of Vaporization", Chem. Ing. Tech. 26, 679 (1955).
7. Riedel, L., "A New Universal Vapor-Pressure Equation. IV. Compressibility, Surface Tension, and Thermal Conductivity in the Liquid Phase", Chem. Ing. Tech. 27, 209 (1955).
8. Uhler, A., Jr., "Thermal Conductivity of Fluid Argon and Nitrogen", J. Chem. Phys. 20, 472 (1952).

Of the various sets of experimental data used in presenting the thermal conductivity of saturated liquid nitrogen as shown in Figure 30, the data of Powers, et al (3), were weighed most heavily over the temperature range from -336.1 to -301.1°F. At higher temperatures, the correlation of Owens and Thodos (2) received more consideration in plotting. The data of Borovik, et al (1) showed excessive positive deviations from the rest of the data at lower temperatures, from -328 to -301°F, but agreed well with Owens and Thodos (2) over the higher temperature ranges. The correlation of Riedel (4, 5, 6, 7) as well as most of the values

from Uhlir (8) showed large negative deviations from the plotted curve. Values of thermal conductivity for the lower temperatures as taken from references (1, 4, 5, 6, 7, 8) resulted in large deviations from the curve. In plotting, however, they were almost completely ignored, and the resulting agreement between the value of references (3) and (2) is good, being on the order of $\pm 2-3\%$ which is approximately average uncertainty of the correlation of Reference (2). The correlation of Riedel (4, 5, 6, 7) on the other hand, has a maximum uncertainty of about 10%, and these values were therefore given little weight.

The tabulated data are given in Table X.

I. Thermal Conductivity of Saturated Liquid Oxygen

Sources of Data:

1. Hilsenrath, J., et al, "Tables of Thermal Properties of Gases", NBS Circ. 564, (1955) p. 425.
2. Johnson, V. J., "A Compendium of the Properties of Materials at Low Temperatures" (Phase I) WADD-TR-60-56, Oct., 1960, p. 3.005.
3. Owens, E. J. and G. Thodos, "Thermal Conductivity-Reduced State Correlation for the Inert Gases", A. I. Ch. E. Journal **3**, 459-60 (1957).
4. Scott, R. B., "The Density of Liquid Oxygen", NBS Rep. 6752, 1-2 (1961).
5. Tsederberg, N. V. and D. L. Timrot, "Experimental Determination of Thermal Conductivity of Liquid Oxygen", Zhur. Tekh. Fiz. **26**, 1849-56 (1956).
6. Ziebland, H. and J. T. A. Burton, "The Thermal Conductivity of Liquid and Gaseous Oxygen", Brit. J. Appl. Phys. **6**, 416 (1955).

The data calculated using the equations of Tsederberg and Timrot (5) were given primary weight in plotting the thermal conductivity of saturated liquid oxygen given in Figure 31. These equations were used to calculate values of the thermal conductivity over the range, -360°F to -181°F . Although the equations specifically exclude a transition range near the critical point, values of thermal conductivity in the range of -213° to -183°F were computed using the equation for the lower temperatures. Agreement with values from Ziebland and Burton (6) at the same temperatures was very good, although these values were not subsequently graphed. The values of thermal conductivity at other temperatures from Ziebland and Burton (6) which are graphed, show small negative deviations from the smoothed curve of not more than 2%. This source was not given primary weight since values were read from a graph. Data from the other two sources, Owens and Thodos (3), and the NBS Compendium (2) are plotted for

comparison only. The deviations occurring when the correlation of Owens and Thodos (3) is used for liquid oxygen are as high as 37.4%, according to the authors. The saturated liquid curve given in the NBS Compendium (2) is only an estimate. The values from references (2) and (3) were therefore accorded no weight in plotting. Hence, if these data points are ignored, the uncertainty of the smoothed curve becomes $\pm 2\%$.

The tabulated data are given in Table XI.

J. Density of Oxygen

Sources of Data:

Liquid and Vapor

The sources of data used in plotting the isobars for the gaseous oxygen densities as given in Figure 32 were taken from the Leiden Chart (4) and Hilsenrath et al (3), from the latter of which data points were calculated from a virial equation of state. The largest errors in these values, according to Hilsenrath et al (3), occur at low density due to fitting the second virial coefficient imperfectly, and may be as high as 3% of the deviation from ideality. However, over the range that this data was used 10 to 1500 PSIA, and -280°F to 116.3°F, the uncertainty in the density values should be well within + 1%. Data from the Leiden Chart (4) were used with values from Hilsenrath (3) up to 1500 PSIA, and were used

exclusively at higher pressures, up to 4000 PSIA.

The values from both sources correlate very well; the deviation and data points about the isobars is very small, the uncertainty estimated to be within $\pm 1\%$.

The tabulated data are given in Table XII.

Saturated Liquid

The most recently experimental results are those of Van Itterbeek and Verbeke (8) who report measured values over the temperature range, -343.3 to -297.2°F . From these values, an equation for saturation density was given by these investigations, and this equation was used to compute values up to -195°F . According to Scott (6), the densities up to about 95°K (-288.7°F) are reliable to within 0.1% . This uncertainty increases with increasing temperature, perhaps reaching 0.5% at 125°K (-234.7°F). An increased uncertainty may be assumed at temperatures above 125°K . The data of Van Itterbeek (7) cover the range, -349.9° to -297.7°F . Primary weight in plotting the saturated liquid density of oxygen as shown in Fig. 33 was given to the values from both references (7) and (8) over the common temperature range, while at higher temperatures, the calculated and experimental values from reference (8) were given primary weight.

Although the values from Mathias and Onnes (5) are more precise than those of Van Itterbeek (7), they are not as recent, and were consequently given secondary weight in plotting the curve. The average deviation of the points of Mathias and Onnes (5) from the curve is approximately $\pm 1\%$. Points calculated from the reduced-state correlation of Byrne and Thodos (1) are also plotted, and according to these authors, the uncertainty in the oxygen values thus obtained averages about 0.9% with maximum values approaching 5% . The variation of data points about the smoothed curve is \pm or less.

In summary, it is probable that the uncertainty of values obtained from the curve does not exceed $\pm 1\%$.

The tabulated data are given in Table XIII.

Saturated Vapor

The major data source used in plotting the saturated vapor curve given in Fig. 34 was the Leiden Chart (4) from which density values over the temperature range, -303.5 to -184°F , were plotted. At lower temperatures, -328.7 to -300°F , several series of density values at given pressures from Hilsenrath (3) were extrapolated to the saturation temperature, as determined from the vapor pressure of oxygen (2). Using these extrapolated points as a guide, the saturated vapor line was thus extended to the lower temperatures. The other data source used was the correlation of Byrne and Thodos (1) from which the values plotted covered the temperature range, -209° to -181.1°F . The average deviation of the values from experimental values is less than $\pm 1\%$.

All of the data sources were given equal weight in plotting the curve, since all the data appeared to be consistent. The deviation of data points about the curve is small in most cases less than 1% , although deviations of up to $\pm 4\%$ are present.

The tabulated data are given in Table XIV.

6. Mathias, E., H. K. Onnes, and C. A. Crommelin, Leiden Comm. 14, No. 145C (1914).

Liquid and Vapor

Two data sources were used almost exclusively in plotting the gaseous density curves shown in Figure 35. These were the Leiden Charts (5) and NBS Circular 564 (3). Both sources furnished values over the entire pressure range, 10 to 1500 PSIA. Values from reference (5) were taken from a crossplot to insure accurate interpolation. Density values from reference (3) were computed directly from a virial equation of state. The parameters and constants were chosen so as to make the values most accurate at moderate and elevated temperatures, greater than 300°K. Hence, the results from reference (3) are less accurate at lower temperatures. Such values were not given primary weight in plotting the curves. Values from the high-pressure density determinations of Benedict (1) were included in plotting the 1500 PSIA isobar. These values were obtained from a crossplot of the Benedict data.

The data sources are in good agreement. The uncertainty in the values from reference (3) are very small at temperatures above 300°K, and, even at lower temperatures, are always less than 1% with the values used. In constructing the isobars near the critical point, results from reference (5) were used exclusively, with the exception of the values from Benedict (1) for the 1500 PSIA isobar, since information from reference (3) about this region tended to be sparse and increasingly uncertain. Values obtained from this region will, however, tend to be more uncertain than values at higher temperatures and lower pressures. Because of the small spread of points about the curves, and the accuracy of the data used, there is confidence that the isobars are accurate to within $\pm 1\%$.

The tabulated data are given in Table XV.

Saturated Liquid (Figure 36)

Since the four data sources (2, 4, 5, 6) used in plotting the saturated liquid nitrogen density as shown on Figure 35 gave consistent results, no particular source was given special weight in drawing the smoothed curve. The values of Byrne and Thodos (2) were correlated as reduced-densities which the authors termed "accurate". This correlation was developed from nitrogen data. The data of Mathias, et al (6) is not recent but is precise and gives consistent density values. The data from reference (4) is actually that of:

- (A) Gerold, E., Ann. Physik 65, 82-96 (1921)
- (B) International Critical Tables, McGraw-Hill Book Co., New York (1927)
- (C) Mathias, E. and Crommelin, C. A., Proc. Fourth Intern. Congress of Refrig. 1, 89-106 (1924)

The values from the Leiden Chart (5) cover a smaller temperature range (-290° to -240°F) than results from the other sources. The data from all the sources cover the range, -343.2°F to -232.6°F. There is virtually no spread of points at all about the smoothed curve at lower temperatures; some deviation occurs near the critical point. The uncertainty in reading the smoothed plot should be well within $\pm 1\%$ at temperatures between -343.2 and -243.9°F, but may reach $\pm 2\%$ near the critical point.

The tabulated data are given in Table XVI.

Saturated Vapor (Figure 37)

The results from the Leiden Chart (5) and the NBS Compendium (4) were quite consistent and were given equal weight in plotting the density of saturated nitrogen vapor shown on Figure 37. The Leiden Chart (5) covered the range, -326° to -240.5°F ; values from the NBS Compendium (4) were plotted over the range, -343.2° to -234.7°F . The tabulated reduced-density values of Byrne and Thodos (2) showed consistent deviations from these data (5) (4). They were included over the temperature range, -323.4° to -232.6°F .

The smoothed plot fits the points well to about -285°F . There is virtually no spread of points from references (5) and (4) at the lower temperatures, although values from reference (2) show deviations up to 4%. At higher temperatures, the number of points deviating from the curve increases, the deviation reaching maximums of $\pm 5\%$. Over the entire temperature range, the uncertainty in values obtained from the curve is probably 2 to 3%.

2. Hall, N. H. and W. E. Ibele, "Thermodynamic Properties of Air, Nitrogen, and Oxygen as Imperfect Gases", Univ. Minn. Inst. Technical Eng. Expt. Sta. Tech. Paper 85, (1951).
3. Hilsenrath, J. et al, "Tables of Thermal Properties of Gases", NBS Circ. 564, 331-333-359 (1955).
4. Johnson, V. J., "A Compendium of the Properties of Materials at Low Temperatures (Phase I)", WADD TR-60-56, Oct., 1960, p. 3.004 and 4.004.

The values of viscosity and thermal conductivity for the saturated liquid and saturated vapor curves, and for the isobars from 500 to 2000 PSIA, inclusive, were read from the viscosity and thermal conductivity graphs Figures 1 and 9 of this report. For the 200 and 300 PSIA isobars, interpolated values of viscosity and thermal conductivity from these graphs were used, except for the temperatures of -171.7 and -135.7°F at 200 PSIA, and the temperature range -207.7 to -99.7°F at 300 PSIA, where data from the NBS Compendium, 3.004 (4) were used. Values of thermal conductivity at constant temperature for various pressure values were read from the plot given in reference (4) and replotted as a curve of thermal conductivity vs. pressure with temperature as a parameter, enabling an accurate interpolation to be made. The Prandtl Number is shown in Figure 38.

For the saturated liquid curve, values of the specific heat were read from the graph, 4.004, of reference (4). This graph can be read with a high degree of precision, approximately, 0.2%. An extrapolation of values found in Hall and Ibele (2) to the saturation temperature was necessary to obtain specific heat values for the saturated vapor. The extrapolated values of specific heat become less reliable as the saturation temperature approaches the critical temperature. At 1 atm., values of specific heat for the calculated nitrogen Prandtl Numbers

were obtained from the data of 4.004 of reference (4) and from NBS Circular 564 (3). In addition, values of the Prandtl Number of nitrogen from reference (3) were plotted at 1 atm; these values were given primary weight, since they correlated well. The specific heat values for the 500 PSIA isobar were taken from three sources: at temperatures above 0°F, reference (3) was used; at lower temperatures (-200 to 0°F), a curve of specific heat vs. temperature was drawn from the series of values, and extrapolated. For the other isobars, specific heat values from reference (3) were most often used, although at lower temperatures some values were taken from references (2) and (4). Data of Deming and Shupe (1) were used to obtain the specific heat on the 2000 PSIA isobar. Obtaining values from reference (3) generally required a double interpolation (temperature and pressure). The data of reference (4) are probably most reliable, but the values of Hall and Ibele (2) are most precise.

It should be noted that the 300 and 1500 PSIA isobars are not plotted; values for the Prandtl numbers at these pressures are included in the tabulated data, however. Both the saturated vapor and saturated liquid curves approach infinity as the temperature approaches the critical point. The reason for this is that at the critical point, the specific heat becomes infinite, while the viscosity and thermal conductivity both remain finite. Because of the lack of data available, the Prandtl Number for the saturated vapor (-320° to -270°F) and for the 200 PSIA isobar (-260° to -180°F) is likely to be most doubtful. The 14.7 and 200 PSIA isobars are drawn as a single line above -120°F, since the Prandtl Number for both isobars indicate that this is the best curve.

The crossing of the 1000 psia and 2000 psia isobars is indicated clearly by the calculations based on the data for the individual properties. However, the differences between these curves never exceed about 5%, which is within the accuracy resulting from the calculations. Thus this intersection may not be a physical fact.

The tabulated data are given in Table XVIII.

M. Prandtl Number of Oxygen

Source of Data:

1. Hall, N. H. and Ibele, W. E., "Thermodynamic Properties of Air, Nitrogen, and Oxygen as Imperfect Gases", Univ. Minn. Inst. Technical Eng. Expt. Sta. Tech. Paper 85 (1957).
2. Hilsenrath, J. et al, "Tables of Thermal Properties of Gases", NBS Cir. 564, 402, 426 (1955).

Prandtl Number values were computed from values of specific heat, viscosity and thermal conductivity in all cases except for values at 14.7 PSIA. Values of viscosity and thermal conductivity for the isobars (14.7 to 2000 PSIA) were read from the graphs of the viscosity and thermal conductivity of gaseous oxygen presented as Figures 2 and 10 of this report. The values for 200 and 400 PSIA were determined by linear interpolation between 14.7 and 500 PSIA. The uncertainty in the interpolated values increases with increasing nonlinearity of the isobars on the viscosity and thermal conductivity and hence increases with decreasing temperature. Values of viscosity and thermal conductivity for the saturated vapor were also read from these graphs. For the saturated liquid, the graphs of thermal conductivity and viscosity for liquefied oxygen (saturated), Figures 4 and 11 of this report, were read.

The specific heat values for the saturated liquid were determined by extrapolating graphically a series of specific heat values near the saturation curve at given pressures. This was done with the aid of the data of Hall and Ibele (1). Specific heat values for the saturated vapor and all of the isobars except 14.7 PSIA were obtained by differencing these data. For the isobar of 14.7 PSIA, specific heat values from NBS Circular 564 (2) were used over the range, +116.3 to +296.3°F. From -279.7 to +98.3°F, values of the Prandtl Number at 1 atm were used from reference (1) directly.

Because the Prandtl Number values at 14.7 PSIA correlated so well, they were used as a guide to the shape of the saturated vapor curve. The 1 atm isobar was extrapolated slightly to the saturation temperature, determining a point on the saturated vapor curve. This curve was then estimated from -300 to -210°F,

using values near the latter temperature. The 200 PSIA isobar did not correlate very well, so that its extrapolation to the saturation temperature did not provide a meaningful check on the shape of the saturation curve. The 400 PSIA isobar could be more accurately plotted, and hence its extrapolation was more meaningful. However, the saturation temperature at 400 PSIA occurs on a part of the saturation curve which is relatively well-defined. Consequently, the most doubtful regions of the curve are (a) the saturated vapor line from -300 to -210°F , and (b) the 200 PSIA isobar from -230 to -160°F .

The resulting graph of the Prandtl Number of oxygen is presented in Figure 39 and the tabulated data are given in Table XIX.

IV. Conclusions and Recommendations

The charts of thermodynamic data presented in this report represent a complete and consistent review of the results of investigators who have published prior to July, 1961. Although data were selected on the basis of consistency and adherence to known physical relationship, the selection was largely a matter of judgement. Those who wish to examine this judgement will find a complete bibliography in Section V, and a tabulation of the data in the Appendix.

The data reported cover a rather narrow range of temperature. It is recommended that similar studies be undertaken by the Air Force to include the solidus region and the superheated gas region to 4000°F.

NOTES:

Cp values from TDB 105.144

 μ and K values from revised graphs.

<p>AIR PRODUCTS and CHEMICALS, Inc., P.O. Box 538, Allentown, Pennsylvania ASD-TR-61-625. THERMODYNAMIC DATA on OXYGEN AND NITROGEN. Final Report. September 1961. 151 Pages (incl. Figures and Tables). 239 References. Unclassified Report</p> <p>The following data, which were compiled from published literature, are presented graphically as a function of temperature and pressure:</p> <p>Viscosity of Nitrogen, Viscosity of Oxygen, Viscosity of Air, Viscosity of Saturated Liquid (Oxygen, Nitrogen, and Mixtures),</p> <p>Over</p>	<p>UNCLASSIFIED</p> <p>Thermodynamic Data Survey</p> <p>I. Project 1-(1-3048) Task 304802 II. AF 33(616)-6287 III. AIR PRODUCTS and CHEMICALS, Inc. Allentown, Pa. IV. Jerome Brewer V. ASD-TR-61-625 VI. Available from OTS VII. In ASTIA Collection</p> <p>UNCLASSIFIED</p>
<p>Vapor-Liquid Equilibrium Ratios: Oxygen- Nitrogen System, Dew Points: Oxygen- Nitrogen System, Bubble Points: Oxygen- Nitrogen System, Thermal Conductivity of Nitrogen, Thermal Conductivity of Oxygen, Thermal Conductivity of Saturated Liquefied Nitrogen and Oxygen, Density of Oxygen, Density of Nitrogen, Prandtl Number of Nitrogen, and Prandtl Number of Oxygen.</p> <p>For each of the above properties a discuss- ion of their critical evaluation was made. Two complete sets of curves were presented, one set with experimental and correlative data points and one set without data points. A complete bibliography of the sources used</p> <p>Continued</p>	<p>UNCLASSIFIED</p> <p>Thermodynamic Data Survey</p> <p>UNCLASSIFIED</p>

<p>for each property are given as well as a master bibliography which include all sources consulted or related to the subject. Tables of tabulated values of the properties used to construct the various graphs are presented.</p>	<p>UNCLASSIFIED</p> <p>Thermodynamic Data Survey</p> <p>UNCLASSIFIED</p>
